How is energy stored on a capacitor expressed?

The energy stored on a capacitor can be expressed in terms of the work done by the battery. Voltage represents energy per unit charge, so the work to move a charge element dq from the negative plate to the positive plate is equal to $V dq$, where V is the voltage on the capacitor.

What is the energy stored in a capacitor E_{CAP} ?

The average voltage on the capacitor during the charging process is $V/2$, and so the average voltage experienced by the full charge q is $V/2$. Thus the energy stored in a capacitor, E_{cap} , is $\frac{1}{2} QV$ where Q is the charge on a capacitor with a voltage V applied. (Note that the energy is not QV , but $QV/2$.)

What is U_C stored in a capacitor?

The energy U_C stored in a capacitor is electrostatic potential energy and is thus related to the charge Q and voltage V between the capacitor plates. A charged capacitor stores energy in the electrical field between its plates. As the capacitor is being charged, the electrical field builds up.

Should high voltage and high energy capacitors be stored with their terminals shorted?

High voltage and high energy capacitors should be stored with their terminals shorted to prevent charge buildup over time. Capacitors used for energy storage are devices which store electrical energy in the form of electrical charge accumulated on their plates.

How do you calculate the energy needed to charge a capacitor?

The total work W needed to charge a capacitor is the electrical potential energy U_C stored in it, or $U_C = W$. When the charge is expressed in coulombs, potential is expressed in volts, and the capacitance is expressed in farads, this relation gives the energy in joules.

Why does a capacitor need a large capacitance value?

Fig. 1), energy is stored in capacitors on the power bus. This requires a large capacitance value because the allowed voltage drop of high-voltage-energy storage (HVES) stores the energy on a capacitor at a higher voltage and then transfers that energy to the power bus during the dropout (see Fig. 3). This allows a smaller capacitor to be used because a

The rechargeable C cell I mentioned above (1.2v, 2.2Ah) holds 9,500 joules. A capacitor holding this much energy at 1.2v would have to be $(2 \times 9,500 / 1.2 \times 1.2) = 13,000$ Farads, so if it helps, you can think of a battery as an enormous capacitor.
