

What is the future of energy storage?

Storage enables electricity systems to remain in balance despite variations in wind and solar availability, allowing for cost-effective deep decarbonization while maintaining reliability. The Future of Energy Storage report is an essential analysis of this key component in decarbonizing our energy infrastructure and combating climate change.

Why do we need a large-scale electrical energy-storage system?

The increasing demand for renewable energy resources, such as solar and wind power, necessitates the development of large-scale electrical energy-storage (EES) systems, for example, for load leveling and peak shaving for the grid energy market [1,2].

How does nanostructuring affect energy storage?

This review takes a holistic approach to energy storage, considering battery materials that exhibit bulk redox reactions and supercapacitor materials that store charge owing to the surface processes together, because nanostructuring often leads to erasing boundaries between these two energy storage solutions.

Why do we need high-energy density energy storage materials?

From mobile devices to the power grid, the needs for high-energy density or high-power density energy storage materials continue to grow. Materials that have at least one dimension on the nanometer scale offer opportunities for enhanced energy storage, although there are also challenges relating to, for example, stability and manufacturing.

What is reversible storage and release of electricity?

Reversible storage and release of electricity is an essential technology, driven by the needs of portable consumer electronics and medical devices, electric vehicles, and electric grids, as well as the emerging Internet of Things and wearable technologies.

Why is energy storage important?

Energy storage is a potential substitute for, or complement to, almost every aspect of a power system, including generation, transmission, and demand flexibility. Storage should be co-optimized with clean generation, transmission systems, and strategies to reward consumers for making their electricity use more flexible.

High-capacity or high-voltage cathode materials are the first consideration to realize the goal. Among various cathode materials, layered oxides represented by LiMO_2 can produce a large theoretical capacity of more than 270 mAh/g and a comparatively high working voltage above 3.6 V, which is beneficial to the design of high energy density LIBs [3].
